Assignment

What does tf-idf mean?

Tf-idf stands for *term frequency-inverse document frequency*, and the tf-idf weight is a weight often used in information retrieval and text mining. This weight is a statistical measure used to evaluate how important a word is to a document in a collection or corpus. The importance increases proportionally to the number of times a word appears in the document but is offset by the frequency of the word in the corpus. Variations of the tf-idf weighting scheme are often used by search engines as a central tool in scoring and ranking a document's relevance given a user query.

One of the simplest ranking functions is computed by summing the tf-idf for each query term; many more sophisticated ranking functions are variants of this simple model.

Tf-idf can be successfully used for stop-words filtering in various subject fields including text summarization and classification.

How to Compute:

Typically, the tf-idf weight is composed by two terms: the first computes the normalized Term Frequency (TF), aka. the number of times a word appears in a document, divided by the total number of words in that document; the second term is the Inverse Document Frequency (IDF), computed as the logarithm of the number of the documents in the corpus divided by the number of documents where the specific term appears.

- **TF:** Term Frequency, which measures how frequently a term occurs in a document. Since every document is different in length, it is possible that a term would appear much more times in long documents than shorter ones. Thus, the term frequency is often divided by the document length (aka. the total number of terms in the document) as a way of normalization:
  $TF(t) = \frac{\text{Number of times term t appears in a document}}{\text{Total number of terms in the document}}.$
- **IDF:** Inverse Document Frequency, which measures how important a term is. While computing TF, all terms are considered equally important. However it is known that certain terms, such as "is", "of", and "that", may appear a lot of times but have little importance. Thus we need to weigh down the frequent terms while scale up the rare ones, by computing the following:
  $IDF(t) = \log_{e}\frac{\text{Total number of documents}}{\text{Number of documents with term t in it}}.$ for numerical stabiltiy we will be changing this formula little bit
  $IDF(t) = \log_{e}\frac{\text{Total number of documents}}{\text{Number of documents with term t in it}+1}.$

Example

Consider a document containing 100 words wherein the word cat appears 3 times. The term frequency (i.e., tf) for cat is then (3 / 100) = 0.03. Now, assume we have 10 million documents and the word cat appears in one thousand of these. Then, the inverse document frequency (i.e., idf) is calculated as log(10,000,000 / 1,000) = 4. Thus, the Tf-idf weight is the product of these quantities: 0.03 * 4 = 0.12. </p>

Task-1

1. **Build a TFIDF Vectorizer & compare its results with Sklearn:**

- As a part of this task you will be implementing TFIDF vectorizer on a collection of text documents.

- You should compare the results of your own implementation of TFIDF vectorizer with that of sklearns implemenation TFIDF vectorizer.

- Sklearn does few more tweaks in the implementation of its version of TFIDF vectorizer, so to replicate the exact results you would need to add following things to your custom implementation of tfidf vectorizer:
    1. Sklearn has its vocabulary generated from idf sroted in alphabetical order
    2. Sklearn formula of idf is different from the standard textbook formula. Here the constant **"1"** is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions. $IDF(t) = 1 + \log_e \frac{1 + \text{Total number of documents in collection}}{1 + \text{Number of documents with term t in it}}$.
    3. Sklearn applies L2-normalization on its output matrix.
    4. The final output of sklearn tfidf vectorizer is a sparse matrix.

- Steps to approach this task:
    1. You would have to write both fit and transform methods for your custom implementation of tfidf vectorizer.
    2. Print out the alphabetically sorted voacb after you fit your data and check if its the same as that of the feature names from sklearn tfidf vectorizer.
    3. Print out the idf values from your implementation and check if its the same as that of sklearns tfidf vectorizer idf values.
    4. Once you get your voacb and idf values to be same as that of sklearns implementation of tfidf vectorizer, proceed to the below steps.
    5. Make sure the output of your implementation is a sparse matrix. Before generating the final output, you need to normalize your sparse matrix using L2 normalization. You can refer to this link https://scikit-learn.org/stable/modules/generated/sklearn.preprocessing.normalize.html
    6. After completing the above steps, print the output of your custom implementation and compare it with sklearns implementation of tfidf vectorizer.
    7. To check the output of a single document in your collection of documents, you can convert the sparse matrix related only to that document into dense matrix and print it.

Note-1: All the necessary outputs of sklearns tfidf vectorizer have been provided as reference in this notebook, you can compare your outputs as mentioned in the above steps, with these outputs.
Note-2: The output of your custom implementation and that of sklearns implementation would match only with the collection of document strings provided to you as reference in this notebook. It would not match for strings that contain capital letters or punctuations, etc, because sklearn version of tfidf vectorizer deals with such strings in a different way. To know further details about how sklearn tfidf vectorizer works with such string, you can always refer to its official documentation.
Note-3: During this task, it would be helpful for you to debug the code you write with print statements wherever necessary. But when you are finally submitting the assignment, make sure your code is readable and try not to print things which are not part of this task.

Corpus

In [0]:

```
## SkLearn# Collection of string documents

corpus = [
     'this is the first document',
     'this document is the second document',
     'and this is the third one',
     'is this the first document',
]
```

SkLearn Implementation

In [0]:

```
from sklearn.feature_extraction.text import TfidfVectorizer
vectorizer = TfidfVectorizer()
vectorizer.fit(corpus)
skl_output = vectorizer.transform(corpus)
```

In [3]:

```
# sklearn feature names, they are sorted in alphabetic order by default.

print(vectorizer.get_feature_names())
```

```
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
```

In [4]:

```
# Here we will print the sklearn tfidf vectorizer idf values after applying the fit metho
d
# After using the fit function on the corpus the vocab has 9 words in it, and each has it
s idf value.

print(vectorizer.idf_)
```

```
[1.91629073 1.22314355 1.51082562 1.         1.91629073 1.91629073
 1.         1.91629073 1.        ]
```

In [5]:

```
# shape of sklearn tfidf vectorizer output after applying transform method.

skl_output.shape
```

Out[5]:

```
(4, 9)
```

In [6]:

```
# sklearn tfidf values for first line of the above corpus.
# Here the output is a sparse matrix

print(skl_output[0])
```

```
  (0, 8)	0.38408524091481483
  (0, 6)	0.38408524091481483
  (0, 3)	0.38408524091481483
  (0, 2)	0.5802858236844359
  (0, 1)	0.46979138557992045
```

In [7]:

```
# sklearn tfidf values for first line of the above corpus.
# To understand the output better, here we are converting the sparse output matrix to den
se matrix and printing it.
# Notice that this output is normalized using L2 normalization. sklearn does this by defa
ult.

print(skl_output[0].toarray())
```

```
[[0.         0.46979139 0.58028582 0.38408524 0.         0.
  0.38408524 0.         0.38408524]]
```

Custom implementation of TF-IDF Vcetorizer

Task - 1

In [0]:

```
# Write your code here.
```

```
# Make sure its well documented and readble with appropriate comments.
# Compare your results with the above sklearn tfidf vectorizer
# You are not supposed to use any other library apart from the ones given below

from collections import Counter
from tqdm import tqdm
from scipy.sparse import csr_matrix
import math
import operator
from sklearn.preprocessing import normalize
import numpy
```

This fit function will return (Vocabulary ,TF_IDF) values

1. Will return Voacbulary as dict
2. Will return idf_vales as dict

fit_TF_IDF

In [0]:

```
#creating a vocabulary using fit method
def fit_TF_IDF(corpus):

  # ***************************Part - 1 --> Creating Vocabulary ************************
*******
  unique_words =set()

  if isinstance(corpus, (list,)):
    for doc in corpus:
      for word in doc.split():
        if len(word) < 2:
          continue
        unique_words.add(word)

    unique_words = sorted(unique_words)
    vocab = {word:idx for idx,word in enumerate(unique_words)}
    #print(vocab)

  # ***************************Part - 2 --> Computing IDF values ***********************
********

    N = len(corpus)            # Total no of docs in corpus
    idf_values = dict()        # {'and': 2.09861} -- word:idf_value as dictionary

    for word in vocab.keys():
      n = 0      # of docs in which req word is present
      for doc in corpus:
        if word in doc.split():
          n+=1
      idf_values[word] = 1+math.log((1+N)/(1+n))
    return vocab,idf_values

  else:
    print('Please enter the input corpus as a list')
```

In [10]:

```
corpus = ['this is the first document' ,
          'this document is the second document',
          'and this is the third one',
          'is this the first document']

vocab,idf_dict = fit_TF_IDF(corpus)

print(vocab,'\n')
print(idf_dict.values())
```

```
{'and': 0, 'document': 1, 'first': 2, 'is': 3, 'one': 4, 'second': 5, 'the': 6, 'third':
7, 'this': 8}

dict_values([1.916290731874155, 1.2231435513142097, 1.5108256237659907, 1.0, 1.9162907318
74155, 1.916290731874155, 1.0, 1.916290731874155, 1.0])
```

These IDF Values are matching with the above Sklearn's fit method idf values. So, proceeding to transform method

transform_TF_IDF

In [0]:

```
def transform_TF_IDF(new_corpus,vocab,idf_dict):

  rows =[]
  columns =[]
  tfidf_values = []

  if isinstance(new_corpus,(list,)):
    for row_idx,doc in enumerate(new_corpus):
      doc_list = doc.split()
      for word in set(doc_list):   ##Please read the note with Heading 'why set(doc_list)?
'
        col_idx = vocab.get(word,-1)
        if col_idx == -1:
          continue
        columns.append(col_idx)      #appending col num: value of a word in Vocab dict
        rows.append(row_idx)         #appending row num : Row number from the corpus or d
ocument no

        tf = ( doc_list.count(word) / len(doc_list) )
        idf = idf_dict.get(word)
        tfidf_values.append(tf*idf)
    sparse_tfidf_output = csr_matrix((tfidf_values,(rows,columns)),shape = (len(new_corp
us),len(vocab)) )  #check csr_matrix? initialisations
    sparse_tfidf_output = normalize(sparse_tfidf_output)             #Applying L2 norm a
nd is explained clearly in the below cells

    return sparse_tfidf_output

  else:
    print('Please input the new_corpus as a list')
```

In [12]:

```
corpus = ['this is the first document' ,
          'this document is the second document',
          'and this is the third one',
          'is this the first document']

vocab,idf_dict = fit_TF_IDF(corpus)

output = transform_TF_IDF(corpus,vocab,idf_dict)
print(output.toarray()[0])
```

```
[0.         0.46979139 0.58028582 0.38408524 0.         0.
 0.38408524 0.         0.38408524]
```

I know i shud not use any extra modules #But using pandas here for only to display the output properly

In [13]:

```
import pandas as pd
print('---------------------Displaying Custom made TF_IDF output -----------------\n')
pd.DataFrame(output.toarray() , columns = vocab )
```

```

These TF-IDF Values are matching with the above Sklearn's transform method TF-IDF values.

Note: Explaination of L2 Norm

L2 Norm of matrix https://machinelearningmastery.com/vector-norms-machine-learning/

For Normalisation of a matrix using sklearn.preprocessing.normalize

Ex :

A = [[1 2 3 4]]

L2 Normalization custom made without using SkLearn

In [15]:

```
import math

A = [1,2,3,4]
sum_of_sq = sum([x**2 for x in A])
#print(sum_of_sq)
A_norm = [x/math.sqrt(sum_of_sq) for x in A]
print(A_norm)
```

```
[0.18257418583505536, 0.3651483716701107, 0.5477225575051661, 0.7302967433402214]
```

L2 Normalization using sklearn.preprocessing.normalize

In [16]:

```
from sklearn.preprocessing import normalize
normalize([[1,2,3,4]])
```

Out[16]:

```
array([[0.18257419, 0.36514837, 0.54772256, 0.73029674]])
```

In [0]:

In [0]:

```

```

In [0]:

```

```

Creation of Sparse matrices using *csr_matrix((values, (rows,columns)))*

In [17]:

```
#Creation of CSR_MATRIX sparse matrix using
# csr_matrix((values,(rows,columns)), shape = (x,y))

values =[10,20,30,40]
rows=[0,1,2,3]
columns=[0,1,2,3]
print( csr_matrix((values,(rows,columns)), shape = (4,4)).toarray() )

#intution rows[0],columns[0] = values[0]
# 0,0 = 10
# 1,1 = 20
```

```
[[10  0  0  0]
 [ 0 20  0  0]
 [ 0  0 30  0]
 [ 0  0  0 40]]
```

In [18]:

```
#re assigning a value to same index will add to previous value
#In the above At A - 0,0 = 10 is there
#if I again assign 0,0 as 12 it will go add to prev values

values =[10,20,30,40, 12]
rows=[0,1,2,3 ,0]
columns=[0,1,2,3 ,0]
print( csr_matrix((values,(rows,columns)), shape = (4,4)).toarray() )

# if u see lat element of rows and cols I am taking zeros
# that is I am assigning a value to 0,0 index in Marix
# first 0,0 = 10
# last 0,0 = 12
# new value at 0,0 will be 10+12 =22
```

```
[[22  0  0  0]
 [ 0 20  0  0]
 [ 0  0 30  0]
 [ 0  0  0 40]]
```

why use set(doc_list) in transform method ?

So when we have same word multiple times in a documnet of corpus,

if we dont use set(doc_list) the we might end up in calculating the IDF value for word 'document' in 2 document of corpus it will effect ten sparse matrix values that we are computing

So, Compute idf values for unique words of a document

In [0]:

```

```

In [0]:

```

```

Task-2

2. Implement max features functionality:

- As a part of this task you have to modify your fit and transform functions so that your vocab will contain only 50 terms with top idf scores.

- This task is similar to your previous task, just that here your vocabulary is limited to only top 50 features names based on their idf values. Basically your output will have exactly 50 columns and the number of rows will depend on the number of documents you have in your corpus.

- Here you will be give a pickle file, with file name **cleaned_strings**. You would have to load the corpus from this file and use it as input to your tfidf vectorizer.

- Steps to approach this task:
  1. You would have to write both fit and transform methods for your custom implementation of tfidf vectorizer, just like in the previous task. Additionally, here you have to limit the number of features generated to 50 as described above.
  2. Now sort your vocab based in descending order of idf values and print out the words in the sorted voacb after you fit your data. Here you should be getting only 50 terms in your vocab. And make sure to print idf values for each term in your vocab.
  3. Make sure the output of your implementation is a sparse matrix. Before generating the final output, you need to normalize your sparse matrix using L2 normalization. You can refer to this link https://scikit-learn.org/stable/modules/generated/sklearn.preprocessing.normalize.html
  4. Now check the output of a single document in your collection of documents, you can convert the sparse matrix related only to that document into dense matrix and print it. And this dense matrix should contain 1 row and 50 columns.

In [19]:

```
from google.colab import drive
drive.mount('/content/drive')
```

```
Drive already mounted at /content/drive; to attempt to forcibly remount, call drive.mount
("/content/drive", force_remount=True).
```

In [20]:

```
# Below is the code to load the cleaned_strings pickle file provided
# Here corpus is of list type

import pickle
with open('/content/drive/My Drive/AA Colab Notebooks/cleaned_strings', 'rb') as f:
    corpus = pickle.load(f)

# printing the length of the corpus loaded
print("Number of documents in corpus = ",len(corpus))
```

```
Number of documents in corpus =  746

Transform method

In [0]:

```
from sklearn.preprocessing import normalize

def transform_TF_IDF(new_corpus,vocab,idf_dict):

  rows =[]
  columns =[]
  tfidf_values = []

  if isinstance(new_corpus,(list,)):
    for row_idx,doc in enumerate(new_corpus):
      doc_list = doc.split()
      for word in set(doc_list):   ##Please read the note with Heading 'why set(doc_list)?'
        col_idx = vocab.get(word,-1)
        if col_idx == -1:
          continue
        columns.append(col_idx)      #appending col num: value of a word in Vocab dict
        rows.append(row_idx)         #appending row num : Row number from the corpus or document no

        tf = ( doc_list.count(word) / len(doc_list) )
        idf = idf_dict.get(word)
        tfidf_values.append(tf*idf)
    sparse_tfidf_output = csr_matrix((tfidf_values,(rows,columns)),shape = (len(new_corpus),len(vocab)) )  #check csr_matrix? initialisations
    sparse_tfidf_output = normalize(sparse_tfidf_output)          #Applying L2 norm and is explained clearly in the below cells

    return sparse_tfidf_output

  else:
    print('Please input the new_corpus as a list')
```

In [26]:

```
new_vocab,new_idf_dict = fit_TF_IDF(corpus)

output = transform_TF_IDF(corpus,new_vocab,new_idf_dict)
print(output.shape)
print(output.toarray()[0])
```

```
(746, 50)
[0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0.
 0. 0. 0. 0. 0. 0. 1. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0. 0.
 0. 0.]
```

I know i shud not use any extra modules #But using pandas here for only to display the output properly

In [27]:

```
import pandas as pd
print('---------------------Displaying Custom made TF_IDF output -----------------\n')
pd.DataFrame(output.toarray() , columns = vocab )
```

```
---------------------Displaying Custom made TF_IDF output -----------------
```
